The violation of symmetry between the time series of elongation and contraction rates of phase-space point spacings is studied to examine the chaos in perturbed harmonic oscillator systems. A transition from integrability to nonintegrability is quantitatively evaluated by introducing a correlation coefficient for the degree of symmetry violation. A feature of the correlation coefficient is discussed, suggesting a possible advantage over the Lyapunov exponent. The relationship between a fluctuation property based on symmetry violation and nonintegrability is also discussed.

§1. Introduction

We demonstrate the characterization of chaos by exploiting a correlation coefficient for a rate of elongations and contractions of consecutive phase-space point spacings. In the case of an integrable orbit on a Poincaré section plane,^{1),2)} it is found that a degree of symmetry occurs between the elongation and contraction rates of the consecutive phase-space point spacings. When this symmetry occurs, the absolute value of the correlation coefficient becomes 1.0. On the other hand, the symmetry of the rates of elongation and contraction is violated when integration becomes impossible, and the absolute values of correlation coefficients are close to zero. This analysis provides us with a new method of considering how the nonintegrabilities depend on the degree of symmetry violation between the elongations and contractions of consecutive phase-space point spacings in perturbed harmonic oscillator systems. We compare the information obtained from the absolute value of the correlation coefficient with that obtained from the Lyapunov exponent^{1),2)} and show the advantage of using the correlation coefficient. Moreover, we show that a fluctuation property derived from the consecutive phase-space point spacings follows the shape of a non-Gaussian distribution function as the degree of symmetry violation increases.

§2. Consecutive phase-space point spacings

To begin with, let us define l_n . The spacing of consecutive phase-space points on the Poincaré section plane is defined as $l_n \equiv \sqrt{(q_{n+1} - q_n)^2 + (p_{n+1} - p_n)^2}$. Here, n enumerates a set of points on the Poincaré section plane. The scaled spacings of l_n is defined as $L_n \equiv l_n \cdot (\bar{l}_n)^{-1}$, where the bar denotes a "spacing average" over all spacings. The spacings were scaled to make $\bar{L}_n = 1.0$. The following modified

nondimensional $SU(3)$ Hamiltonian^{3),4)} was adopted in analyzing L_n :

$$H(q^{(1)}, p^{(1)}; q^{(2)}, p^{(2)}) = 2\mathcal{E}^{(0)}r^2 + \mathcal{E}^{(1)}\frac{(q^{(1)})^2 + p^{(1)2}}{2} + \mathcal{E}^{(2)}\frac{(q^{(2)})^2 + p^{(2)2}}{2} \\ + V^{(1)}\frac{2(\mathcal{N}-1)}{\mathcal{N}}r^2(q^{(1)2} - p^{(1)2}) + V^{(2)}\frac{2(\mathcal{N}-1)}{\mathcal{N}}r^2(q^{(2)2} - p^{(2)2}), \quad (2.1)$$

where $r \equiv \frac{1}{2}\sqrt{2\mathcal{N} - q^{(1)2} - p^{(1)2} - q^{(2)2} - p^{(2)2}}$, and $V^{(1)}$ and $V^{(2)}$ denote the strength of perturbation interaction in each degree of freedom. The system with the Hamiltonian in Eq. (2.1) consists of three single-particle levels with energies $\mathcal{E}^{(0)}$, $\mathcal{E}^{(1)}$, and $\mathcal{E}^{(2)}$, where each level has $\mathcal{N}$ -fold degeneracy. All subsequent analysis assumes that $V^{(1)} = V^{(2)} = V$. In our numerical calculation, we used $\mathcal{N} = 30$, and the single-particle energies were $\mathcal{E}^{(0)} = 0$, $\mathcal{E}^{(1)} = 1$, and $\mathcal{E}^{(2)} = 2$. The position at time t is written as $q_n^{(1)}$, and the position at time $t + \epsilon$ is written as $q_{n+1}^{(1)}$, where ϵ represents the time step of our simulation.

The succession of mappings with the Hamiltonian in Eq. (2.1) is approximated as

$$\begin{aligned} q_{n+1}^{(1)} &= q_n^{(1)} + \frac{\partial H(q_n^{(1)}, p_n^{(1)}; q_n^{(2)}, p_n^{(2)})}{\partial p_n^{(1)}}\epsilon, \\ p_{n+1}^{(1)} &= p_n^{(1)} - \frac{\partial H(q_n^{(1)}, p_n^{(1)}; q_n^{(2)}, p_n^{(2)})}{\partial q_n^{(1)}}\epsilon, \\ q_{n+1}^{(2)} &= q_n^{(2)} + \frac{\partial H(q_n^{(1)}, p_n^{(1)}; q_n^{(2)}, p_n^{(2)})}{\partial p_n^{(2)}}\epsilon, \\ p_{n+1}^{(2)} &= p_n^{(2)} - \frac{\partial H(q_n^{(1)}, p_n^{(1)}; q_n^{(2)}, p_n^{(2)})}{\partial q_n^{(2)}}\epsilon. \end{aligned} \quad (2.2)$$

Hereafter the discussion focuses on $q^{(1)}$ and $p^{(1)}$, which are written as q and p for simplicity.

Fig. 1. Poincaré section plane for the $SU(3)$ Hamiltonian with (a) $V = -0.009$, (b) $V = -0.045$, and (c) $V = -0.110$.

If the interaction V is sufficiently small, the Poincaré section map turns out to be closed curves, as shown in Fig. 1(a). Many orbits form invariant curves in this map, like Fig. 1(a), as guaranteed by the KAM theorem.^{1),2)} In this weak-interaction case, the time dependence of L_n turns out to be periodic, as shown in Fig. 2(a) and Fig. 3(a). The alternating behavior of L_n for this case is shown in more detail in Fig. 2(d). The value of L_n is distributed in the range 0.943 to 1.03, giving a distribution width of 0.087. As is clearly seen from Fig. 3(a), the Fourier components⁵⁾ expressing the mixing effects from other periodic orbits are small in the case of a small interaction $V = -0.009$. Comparing Fig. 3(a) with Fig. 3(b), one can see that the peak of the Fourier coefficients becomes continuous when the interaction strength increases from $V = -0.009$ to $V = -0.045$. As the interaction strength increases further, the chaotic region begins to spread out from the hyperbolic fixed points. This is shown in Fig. 1(c). In this chaotic case, the value of L_n is distributed in a wider range from 0.0 to 2.0, giving a distribution width of 2.0, and the periodicity of L_n disappears, as shown in Fig. 2(c) and Fig. 3(c). A set of peaks extending from $n = 0$ to $n = 5018$ and beyond with no clear maxima in the Fourier coefficients of consecutive point spacings reflects the nonintegrability of the orbit.

Fig. 2. Consecutive phase-space point spacings computed using (a) $V = -0.009$, (b) $V = -0.045$, and (c) $V = -0.110$. The data set of Fig. 1(a)-(c) was used. (d) Short-time development of L_n for $V = -0.009$.

Fig. 3. Root-mean-square of Fourier cosine coefficients and Fourier sine coefficients for the consecutive phase-space point spacings depicted in Fig. 2. (a) $V = -0.009$, (b) $V = -0.045$, and (c) $V = -0.110$.

§3. Symmetry violation for consecutive phase-space point spacings and the relationship to chaos

We will now examine a quantitative estimate of chaos that uses the absolute value of the correlation coefficient for the rates of elongation and contraction of L_n . In the case where $\frac{L_{n+1}}{L_n} > 1$, the rate of elongation is defined as $R_m \equiv \frac{L_{n+1}}{L_n}$, and in the case where $\frac{L_{n+1}}{L_n} < 1$, the rate of contraction is defined as $r_m \equiv \frac{L_{n+1}}{L_n}$. For example, the values $\frac{L_2}{L_1} = 1.1$, $\frac{L_3}{L_2} = 1.2$, $\frac{L_4}{L_3} = 0.9$, $\frac{L_5}{L_4} = 0.8$, $\frac{L_6}{L_5} = 1.3$, and $\frac{L_7}{L_6} = 0.7$ give rise to elongation rates $R_1 = 1.1$, $R_2 = 1.2$, and $R_3 = 1.3$ and contraction rates $r_1 = 0.9$, $r_2 = 0.8$, and $r_3 = 0.7$. The average rates of elongation and contraction for a number M of phase-space point spacings are given by

$$\bar{R} = \frac{1}{M} \sum_{m=1}^M R_m, \quad \bar{r} = \frac{1}{M} \sum_{m=1}^M r_m. \quad (3.1)$$

One may introduce a correlation coefficient⁶⁾ for R_m and r_m that takes the form

$$C_{R_m r_m} = \frac{\sum_{m=1}^M (R_m - \bar{R})(r_m - \bar{r})}{\sqrt{\sum_{m=1}^M (R_m - \bar{R})^2} \sqrt{\sum_{m=1}^M (r_m - \bar{r})^2}}. \quad (3.2)$$

Now, let us begin our analysis by considering the regular-to-chaos transition visible in Figs. 1(a)-(c) and Figs. 2(a)-(c). Since the consecutive phase-space point spacings are periodic in the case of a weak interaction, the time dependences of R_m and r_m are symmetric with respect to $\frac{L_{n+1}}{L_n} = 1$, as shown in Fig. 4(a). In this case, the absolute value of the correlation coefficient is close to 1.0. In Fig. 4, note that the time series of R_m and r_m are independent of each other. As the interaction strength increases

only slightly, the orbit appears as shown in Fig. 1(b), and R_m and r_m now behave as shown in Fig. 4(b). This orbit is, however, not integrable and it can be seen that the symmetry between R_m and r_m is approximately maintained as shown in Figs. 4(b) and 4(d). When the interaction strength increases as shown in Fig. 1(c), one may not expect symmetric behavior between R_m and r_m , and this is demonstrated in Fig. 4(c). In this case, as seen from Fig. 5, the absolute values of the correlation coefficients are close to zero.

§4. Features of the correlation coefficient analysis

In this section, the process is analyzed using the absolute value of the correlation coefficient and the Lyapunov exponent, for the case in which the periodic orbit transitions to the nonintegrable orbit.

In the case with weak interaction, the absolute value of the correlation coefficient quickly reaches 1.0 as shown in Fig. 6(a). When the interaction strength increases, the absolute values of the correlation coefficients are close to 0.0, as shown in the plot for $V = -0.110$ in Fig. 6(a).

Fig. 6. (a) Time dependence of the absolute value of the correlation coefficient for Figs. 1(a)-(c). (b) Time dependence of the Lyapunov exponent for Figs. 1(a)-(c). The number of data points in (a) is roughly half that in (b) due to the division into elongation and contraction rates used to calculate the correlation coefficient.

When the orbit is completely integrable, the absolute value of the correlation coefficient has exactly 1.0 as an upper bound. On the other hand, if the orbit is nonintegrable, it has $|C_{R_m r_m}| = 0.0$ as a lower bound. The Lyapunov exponent

takes negative values when the system is integrable and positive values when the system is non-integrable. However, the upper and lower limits of the value of the Lyapunov exponent are not clear, as depicted in Fig. 6(b).

§5. Asymmetric behavior in consecutive phase-space point spacings and nonintegrability in the Hénon-Heiles system

To date, the analysis of $|C_{R_m r_m}|$ has been performed using the specific $SU(3)$ Hamiltonian with fixed energy $E=40$. To confirm the usefulness of our analysis using $|C_{R_m r_m}|$, let us apply our method to the Hénon-Heiles system¹⁾ and also study what happens when the energy of the system is varied.

The Hamiltonian is given by

$$H(q^{(1)}, p^{(1)}; q^{(2)}, p^{(2)}) = \frac{1}{2}(p^{(1)2} + p^{(2)2}) + \frac{1}{2}(q^{(1)2} + q^{(2)2}) + q^{(1)2}q^{(2)} - \frac{1}{3}q^{(2)3}. \quad (5.1)$$

If the energy E is sufficiently small, the Poincaré section map turns out to be integrable, as shown in Fig. 7(a). In this case, it is found that a degree of symmetry occurs between the R_m and r_m as shown in Fig. 8(a). Since this symmetry occurs, the absolute value of the correlation coefficient becomes 0.5091691 shown in Fig. 9(a). In Fig. 7(b), the successive intersections of the trajectory with the Poincaré section plane lie on sixteen closed curves with ten hyperbolic fixed points located at the joins of adjacent closed curves. Nonintegrability appears in the Hénon-Heiles system as energy increases. An example of this at $E = 0.1669$ is shown in Fig. 7(c). From Figs. 8(c) and 9(a), it can be seen that the symmetry between R_m and r_m is violated with the result that the absolute value of the correlation coefficient approaches zero.

Fig. 7. Surfaces of sections for the Hénon-Heiles Hamiltonian with (a) $E = 0.005$, (b) $E = 0.11796899$, and (c) $E = 0.1669$ from numerical integration.

Next, we describe an advantage that the correlation coefficient has when compared with the Lyapunov exponent. The unstable orbit of Fig. 7(b) is divided into two orbits, as depicted in Figs. 10(a)-(b). The absolute value of the correlation

Fig. 8. Elongation rate and contraction rate of phase-space point spacings. (a) $E = 0.005$, (b) $E = 0.11796899$, and (c) $E = 0.1669$. (d) Short-time development of $\frac{L_{n+1}}{L_n}$ for $E = 0.11796899$.

coefficient for the orbit in Fig. 7(b) is represented by the short dashed line corresponding to $E = 0.11796899$ in Fig. 9(a). The value of $|C_{R_m r_m}|$ markedly varies in the region around $m \approx 2450$ as seen in Fig. 9(a). The corresponding values for the Lyapunov exponent are represented by the short dashed line in Fig. 9(b). As can be seen in those figures, there is a clear change in the absolute value of the correlation coefficient between the sections corresponding to the orbit of Fig. 10(a) and the orbit of Fig. 10(b). The Lyapunov exponent calculation shows the value does not vary markedly with increasing time, as illustrated in Fig. 9(b). In this case, the differing orbits of the two time sections shown in Figs. 10(a)-(b) cannot be distinguished clearly. This suggests a possible advantage of the correlation coefficient over the Lyapunov exponent. The numerical results discussed here show that it is possible to use $|C_{R_m r_m}|$ to sensitively detect even slight changes of orbit, something that the Lyapunov exponent is unable to do.

Fig. 10. The unstable orbit as shown in Fig. 7(b) is composed of orbit (a), which exists in the interval $n = 0$ to $n = 4900$, and orbit (b), which exists in the interval $n = 4901$ to $n = 9990$.

§6. Symmetry violation and probability density distributions

The main topic of this section is the determination of a relationship between a fluctuating property measuring symmetry violation and nonintegrability. To begin with, we define a new variable $O_m = R_m \times r_m$. When the perturbation interaction is sufficiently small, as in Fig. 4(a), this quantity is stationary with a value of $O_m \approx 1.0$ as shown in Fig. 11(a). This corresponds to the case where there is symmetry between R_m and r_m and $|C_{R_m r_m}| \approx 1.0$. This suggests the following equation for the time evolution m when the system is completely integrable.

$$\frac{dO_m}{dm} = 0. \quad (6.1)$$

Fig. 11. Computation of the fluctuation property $O_m = R_m \times r_m$ for perturbation interaction values (a) $V = -0.009$, (b) $V = -0.045$ and (c) $V = -0.110$.

In the case of Figs. 4(b)-(c), the balance between the elongation rate and contraction rate of the phase-space point spacings is broken, and this is confirmed in Figs. 11(b)-(c) as a fluctuation where $\frac{dO_m}{dm} \neq 0$. The statistical properties of this fluctuation are now discussed. To handle the logarithmic behavior between the elongation rate and contraction rates, and hence of O_m , let us introduce the variable Q_m , where

$$Q_m = \begin{cases} O_m - 1 & , \quad O_m \geq 1 \\ 1 - \frac{1}{O_m} & , \quad O_m < 1 . \end{cases} \quad (6.2)$$

Fig. 12. Probability density distribution of Q_m . The width of the histogram dQ_m is 0.05. (a) $V = -0.009$, (b) $V = -0.045$, and (c) $V = -0.110$. The dotted line is the function with the parameter $\alpha = 14.5$ in Eq. (6.3).

For example, the values $O_1 = 2.0$, $O_2 = 5.0$, $O_3 = 10.0$, $O_4 = 0.5$, $O_5 = 0.2$, and $O_6 = 0.1$ correspond to $Q_1 = 1.0$, $Q_2 = 4.0$, $Q_3 = 9.0$, $Q_4 = -1.0$, $Q_5 = -4.0$, and $Q_6 = -9.0$. This variable behaves in a manner similar to O_m for symmetry violations.

We now investigate the distribution of Q_m with increasing nonintegrability. Figures. 12(a)-(c) show the probability density $P(Q_m)$ of finding for the components a value between Q_m and $Q_m + dQ_m$ for each interaction value. The probability density of Q_m behaves as a delta function when the system is integrable, as shown in Fig. 12(a). On the other hand, it becomes a non-Gaussian function as follows, such as that shown in Fig. 12(c) when the nonintegrability is intensified.

$$P(Q_m) = \frac{1}{(Q_m^2 + 1)^{\frac{1+\alpha}{2}}} \quad (6.3)$$

Where the parameter α is fitted by the general least squares procedure.⁶⁾

In the case of the Hénon-Heiles system at an energy of 0.1669, $P(Q_m)$ also shows a function in Eq. (6.3), as can be seen in Fig. 14(c). This corresponds to the fluctuation property O_m in Fig. 13(c).

Note that the statistical property of O_m changes from a delta function to a

function in Eq. (6.3) with increasing perturbation strength. This highlights the importance of O_m as a fluctuating measure of non-integrability in the perturbed harmonic oscillator systems.

Fig. 13. Computation of the fluctuation property $O_m = R_m \times r_m$ for the Hénon-Heiles Hamiltonian with (a) $E = 0.005$, (b) $E = 0.11796899$, and (c) $E = 0.1669$.

§7. Conclusions

We conclude that this analysis provides us with a new method of detecting nonintegrabilities based on the degree of symmetry violation between R_m and r_m . It was demonstrated that slight changes in the properties of unstable orbits, which cannot be distinguished using the Lyapunov exponent, could be detected when using the absolute value of the correlation coefficient.

We also verified numerically that the breaking of symmetry caused the probability density for Q_m to become the function in Eq. (6.3). It is hoped that a distribution function that describes the symmetry violation may be found in the future. Further research on the statistical principle that determines the probability distribution function for generating symmetry violation is needed; thus, statistical mechanics which can describe chaotic motion that breaks the symmetry based on this principle should be constructed.

Fig. 14. Probability density distribution of Q_m . The width of the histogram dQ_m is 0.05. (a) $E = -0.005$, (b) $E = 0.11796899$, and (c) $E = 0.1669$. The dotted line is the function with the parameter $\alpha = 9.9$ in Eq. (6.3).
